a

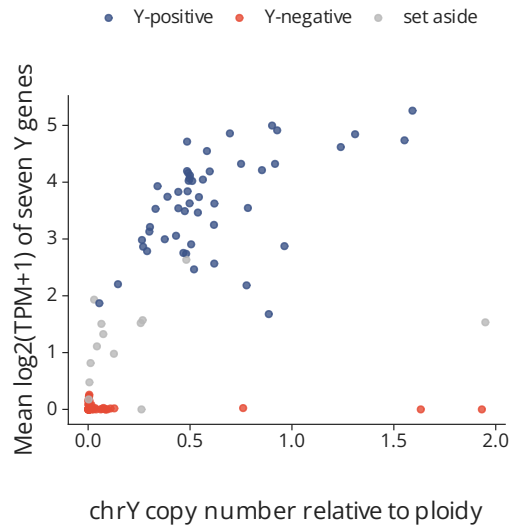

Organoids add 92 models to 58 cell lines in the two cancer types

CRISPR-screened models per Y group. Combined: both sources, as used in the within-type combination.

b

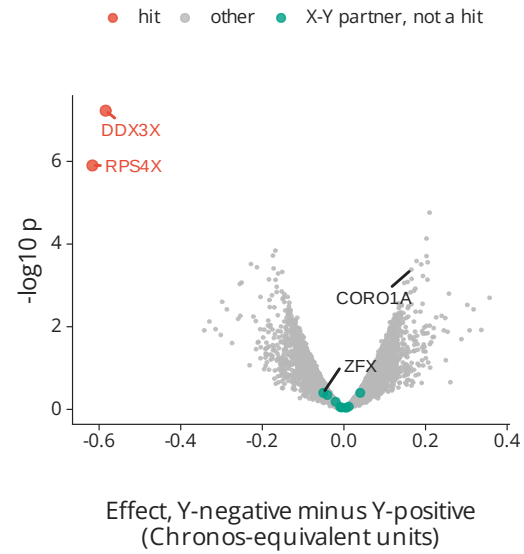

RNA and DNA agree for 88 of 111 screened male organoids

13 set aside: 12 with intermediate RNA, 1 where DNA contradicts RNA. RNA leads where DNA is unclear: 3 Y-negative points at the right express no Y gene but keep most of the male-specific region in DNA, and 2 Y-positive points near zero copy number express all seven Y genes.

c

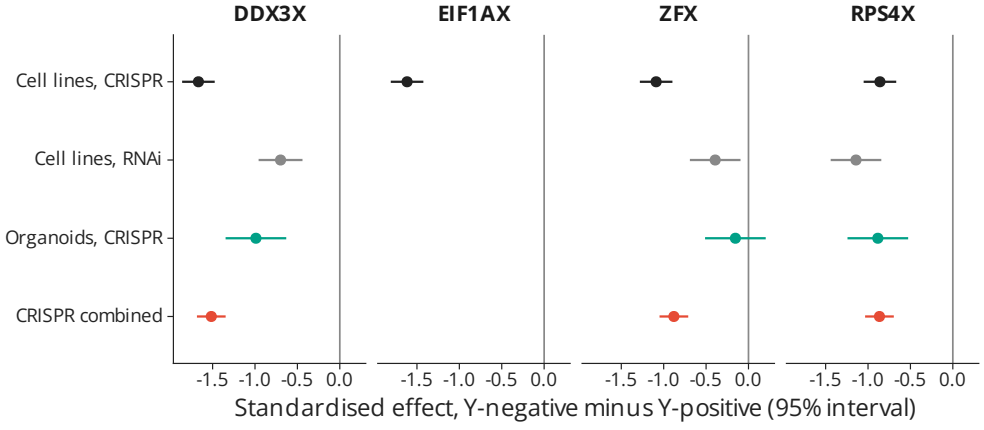

2 genes pass in organoids: DDX3X and RPS4X

16,547 genes, 95 organoids; limma with a weight per organoid; tumour type, library and MSI adjusted.

d

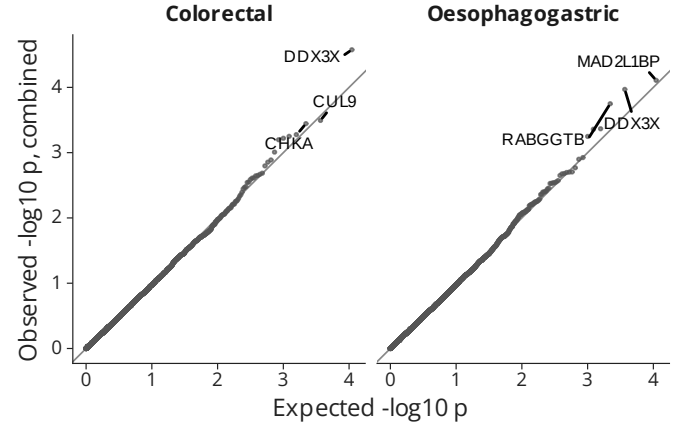

DDX3X and RPS4X hold in every source; ZFX does not in organoids, and EIF1AX is not in their library

Effect in residual SD units of each source, from its own p-value and design. Combined: cell lines and organoids, weighted by design.

e

Within cancer type, the combination finds no gene; DDX3X in colorectal cancer comes closest (FDR 0.15)

5,511 genes per cancer type; rank-based test of the Y effect inside the type in each source, combined by design weight. Red: FDR < 0.05.
